Figure 1. The effect of the concentration of the *Agrobacterium* suspension on the transformation efficiency of *Agrobacterium* strains. The *Agrobacterium* strains were grown in the medium containing 100 mg/l of tetracycline. The cells were harvested at the stationary phase and adjusted to the concentration of 1×10^8 cells/ml. The cells were then mixed with the plant protoplasts and cocultured for 48 h. The cells were then separated from the plant protoplasts and plated on the medium containing 100 mg/l of tetracycline. The transformation efficiency was determined as the number of colonies per 10^6 protoplasts. The results are shown as the mean \pm SD of three independent experiments.

 133.

1. The first step is to identify the key components of the system. This includes understanding the hardware, software, and data involved.

2. The second step is to define the requirements. This involves determining what the system is intended to do and what it must be able to handle.

3. The third step is to design the system. This includes creating a detailed plan of how the system will be built and how it will be tested.

4. The fourth step is to implement the system. This involves building the system according to the design and testing it to ensure it meets the requirements.

5. The fifth step is to maintain the system. This involves keeping the system up-to-date and ensuring it continues to meet the requirements over time.
